CLASSIFYING TOPOS¹ By Jean GIRAUD

The basic facts about the classifying topos of a stack of groupoids were first stated in [3] and are exposed in detail in [4] Ch. VIII. This construction is useful in cohomology theory and has been introduced independently by D. Mumford to study moduli of elliptic curves [7]. Algebraic stacks of groupoids are used in algebraic geometry df. [1]. Here a simpler and more general approach allows us to treat the case of a stack whose fibers are not supposed to be groupoids. As a by-product we get the existence of fibered products in the bicategory of topos. This result was first announced by M. Hakim several years ago but was never published. I suspect that any written prof would have to deal with rather subtle technical difficulties about finite limits which are overcome here by the results of §1.

Is \mathscr{S} is a site we use the word² stack for the french champ [4] and prestack for prechamp (a prestack is merely a fibered category over the underlying category of the site) and split stack for champ scindé. Up to equivalence a split stack can be viewed as a sheaf of categories over \mathscr{S} (or a category-object of the corresponding topos) satisfying some extra condition namely the patching of objects. As usual we choose and fix a universe \mathfrak{U} . For clarity it should be recalled that a \mathfrak{U} -topos is a special case of \mathfrak{U} -site [5] and that any category can be viewed as a site such that any presheaf is a sheaf and prestack is a stack.

²"work" in the original.

1. Left exact stacks

A category is left exact if it admits finite limits. A functor $f:A \longrightarrow B$ between left exact categories A and B is left exact if it preserves finite limits. A site is said to be left exact if the underlying category is so. A stack C over a site S is said to be left exact if its fibers are left exact and if for any map $f:T \longrightarrow S$ in S the inverse image functor induced by f between the fibers of C is left exact.

Lemma (1.1). — A stack C over a left exact site $\mathcal S$ is left exact if and only if the underlying category and the structural functor $p: C \longrightarrow \mathcal S$ are left exact.

The proof rests on the fact that a commutative square of C whose projection is cartesian in \mathcal{S} is cartesian as soon as two opposite sides are \mathcal{S} -cartesian.

Lemma (1.2). — A morphism $m:A\longrightarrow B$ between two left exact stacks is left exact if and only if for any $S\in |\mathcal{S}|^3$ the functor $m_S:A_S\longrightarrow B_S$ induced by m between the fibers at S is left exact.

Proposition (1.3). — Let $f: \mathcal{S}' \longrightarrow \mathcal{S}$ be a morphism between two sites (e.g. two topos). Then the direct image (resp. inverse image) of a left exact stack and of a left exact morphism of stacks over \mathcal{S}' (resp. \mathcal{S}) is left exact.

- **1.3.1.** The direct image of a stack being nothing but pull-back along the underlying functor $f^*: \mathcal{S} \longrightarrow \mathcal{S}'$ of f, preserves the fibers, hence the left exactness. To treat the case of the inverse image by f of a stack over \mathcal{S} we will use the following characterisation⁴ of left-exactness.
- **1.3.2**. First let I be a finite category. For any stack F over \mathscr{S} let F^I be the prestack whose fiber at $S \in |\mathscr{S}|$ is the category of functors from I to the fiber F_S . One checks easily that this is a stack provided with a morphism of stacks (constant diagrams)

$$cF: F \longrightarrow F^{I}$$

Furthermore *F* is left exact if and only if for any finite category *I* c*F* admits a right adjoint in the bicategory of stacks. The if part is obvious since such an adjoint

 $^{^{3}}$ The set of objects of a category C is denoted by |C|

⁴"caracterisation" in the original.

 λ induces an adjoint to each functor cF_S , $S \in |\mathcal{S}|$, induced by cF on the fibers at S and since λ is cartesian. The only if part is no more difficult than (1.2). Since the property of having a right adjoint is preserved by morphisms of bicategories and since the inverse image of stacks is such a morphism [4] p.88, it remains to show the following.

Lemma (1.3.3). — One has a natural equivalence $e: f^*(F^I) \longrightarrow f^*(F)^I$ such that $ef(cF) = cf^*(F)$.

According to [4] p.88, the inverse image of a stack F is given by the formula

$$f^*(F) = Af^{-1}(LF)$$

where LF is the free split stack associated to F [4] p.39, where f^{-1} denotes the inverse image of LF as category-object of the topos $\widetilde{\mathcal{F}}$ and where A stands for "associated stack". Since there is a natural equivalence $f \longrightarrow LF$ and L is a morphism of bicategories we get a natural equivalence of split stack $L(F^I)to(LF)^I$.

Since the functor "inverse image of sheaves of sets" is left exact one gets a natural isomorphism $f^{-1}((LF)^I) \xrightarrow{\sim} (f^{-1}(LF))^I$ and it remains to find, for any prestack G over \mathscr{S}' a natural equivalence $A(G^I) \longrightarrow (AG)^I$. One has a commutative square

$$G \xrightarrow{a} AG$$

$$cG \downarrow \qquad \qquad \downarrow cAG$$

$$G^{I} \xrightarrow{a^{I}} (AG)^{I}$$

where a is the structural map of AG. According to [4] p.77 it suffices to show that a^{I} is "bicouvrant" [4] p.72, which is an easy consequence of the fact that a has this property. Q.E.D..

Corollary (1.4). — Let F and F' be left exact stacks on S and S', $m: F \longrightarrow f_*(F')$ be a morphism of stacks and $m': f^*(F) \longrightarrow F'$ the morphism associated to m by the universal property of the inverse image. Then m is left exact if and only if m' is.

This is a formal consequence of (1.3).

2. Classifying topos of a stack

Proposition (2.1). — Let $\mathcal S$ be a left exact $\mathfrak U$ -site and C a prestack over $\mathcal S$ whose fibers are equivalent to categories which belong to $\mathfrak U$ (C is said to be small). Let us denote by J the coarsest topology on C such that the projection $p:C\longrightarrow \mathcal S$ is a comorphism [5] III 3.1, and by $C-\mathcal S$ the category of sheaves on C for J with values in U.

- (1) J is defined by the pretopology whose covering families are those $(m_i : C_i \longrightarrow C)$, $i \in I \in \mathbb{U}$, such that each m_i is \mathcal{S} -cartesian and such that $p(m_i)$, $i \in I$, is a covering family.
- (2) $C \mathcal{S}$ is a \mathfrak{U} -topos and the morphism $\pi : C \mathcal{S} \longrightarrow \mathcal{S}$ defined by p is essential (i.e. π^* has a left adjoint π ,). If C is left exact then π_1 is left exact.
- (3) If $\mathcal S$ is a $\mathfrak U$ -topos and C is a stack, then the Yoneda functor $\varepsilon:C\longrightarrow C-\mathcal S$ is full and faithful and the composite $C\stackrel{\varepsilon}{\longrightarrow} C-\mathcal S\stackrel{\pi_!}{\longrightarrow} \mathcal S$ is equal to p.

Proof. (1) is an easy consequence of the definition of a comorphism and of the observation made in the proof of (1.1). Let S_a , $a \in A \in \mathbb{U}$, be a family of generators of \mathscr{S} and G_a , $a \in A$, be a subset of $|C_{S_a}|$ which both belongs to \mathbb{U} and contains an element of each isomorphism class of objects of the fiber C_{S_a} . The union of the G_a is a generator of the site (C,J), hence this one is a \mathbb{U} -site and $C-\mathscr{S}$ is a \mathbb{U} -topos. Using (1) one sees easily that for any sheaf F on \mathscr{S} , Fp is a sheaf on C hence $\pi^*(F) = Fp$, hence π^* has a left adjoint hence π is essential. The last assertion of (2) follows from the fact that when C is left exact, p is the underlying functor of a morphism of sites $\mathscr{S} \longrightarrow C$. The fist assertion of (3) follows readily from (1) and the patching condition for morphisms in C. For any $S \in |\mathscr{S}|$, and any $c \in |C_S|$ one has

$$\operatorname{Hom}(\pi_!\varepsilon(c),S) = \operatorname{Hom}(\varepsilon(c),\pi^*(S)) = \pi^*(S)(c) = \operatorname{Hom}(p(c),S)$$

by adjunction, Yoneda and the formula $\pi^*F = F p$, and this concludes the proof.

2.2. Under the assumptions of (2.1), C - S is called the *classifying topos of the* (pre)stack C. Note that a morphism of stacks $m: C \longrightarrow C'$ is a comorphism of

sites and induces a morphism of topos $m - \mathcal{S} : C - \mathcal{S} \longrightarrow C' - \mathcal{S}$. If m is an equivalence, then so is $m - \mathcal{S}$. If C is a split stack one can define a split stack C^V whose fibers are the opposites of the fibers of C. Note that the underlying category of C^V is not the opposite C° of C. Let us consider the category

(1)
$$B_{C}(\mathcal{S}) = \operatorname{St}_{\mathcal{S}}(C^{V}, \operatorname{SH}(\mathcal{S}))$$

of morphisms of stacks $F: C^V \longrightarrow SH(\mathcal{S})$, where $SH(\mathcal{S})$ is the split stack whose fiber at $S \in |\mathcal{S}|$ is the category of sheaves on \mathcal{S}/S (equivalent to \mathcal{S}/S since \mathcal{S} is a topos). One has a natural functor

(2)
$$\tau^* : \mathscr{S} \longrightarrow B_C(\mathscr{S}), \quad \tau^*(S)(c) = \varepsilon(S \times p(c)),$$

where ε is the Yoneda functor of \mathcal{S}/S .

Proposition (2.3). — If $\mathcal S$ is a $\mathfrak U$ -topos and C a split stack one has an equivalence of categories

(1)
$$b: B_C(\mathcal{S}) \longrightarrow C - \mathcal{S}, \quad b(F)(c) = F(c)(p(c))$$

and an isomorphism of functors $b \tau^* \xrightarrow{\sim} \pi^*$.

2.3.1. Note that this proposition proves that $B_C(\mathcal{S})$ is a \mathfrak{U} -topos equivalent to $C-\mathcal{S}$ even when C is not split since one can replace C by an equivalent split stack. Furthermore, by the universal property of the associated stack, $B_C(\mathcal{S})$ is equivalent to $B_{C'}(\mathcal{S})$ when C is the stack associated to some prestack C'.

Furthermore, Lawvere and Tierney have introduced for any category-object E of the topos \mathcal{S} , the topos of objects of \mathcal{S} provided with operations of E. One can prove that this topos is equivalent to $B_C(\mathcal{S})$ where C is the split prestack defined by E hence also equivalent to $C'-\mathcal{S}$, where C' is the stack generated by C. Thus we have three constructions of the classifying topos.

2.3.2. For any split stack D, any map $f: T \longrightarrow S$ in \mathcal{S} and any $s \in |D_S|$ we denote by s^f the inverse image of s by f and by $s_f: s^f \longrightarrow s$ the cartesian map given by the splitting. To define b completely one must define for any $m: c \longrightarrow c'$ in C an application $b(F)(m): b(F)(c') \longrightarrow b(F)(c)$. Let $f = p(m), f: S' \longrightarrow S$. Since C is split there is a canonical factorisation $c' \xrightarrow{m'} c^f \xrightarrow{c_f} c$. Since F

is cartesian one has a canonical isomorphism $i: F(c^f) \longrightarrow F(c)^f$ which for the values at S' (or rather $\mathrm{Id}_{S'}$) of these sheaves induces a bijection $j: F(c^f)(S') \longrightarrow F(c)(f)$ and we take for b(F)(m) the composite

$$F(c)(S) \xrightarrow{f(c)(\dot{f})} F(c)(f) \xrightarrow{\dot{f}^{-1}} F(c^f)(S') \xrightarrow{f(m')(S')} F(c')(S')$$

where $\dot{f}: f \longrightarrow \operatorname{Id}_S$ is the terminal map in \mathscr{S}/S . It is easily checked that b(F) is a functor, recalling that the underlying category of C^V is not the underlying category of C° . The sheaf axiom for b(F) is verified by using (2.1 (1)): for a given family $(c_i \longrightarrow c)$ it is a consequence of the fact that F(c) is a sheaf and F a cartesian functor. The functoriality with respect to F is obvious. To prove that b is an equivalence one constructs explicitly a functor

$$a: C - \mathscr{S} \longrightarrow B_C(\mathscr{S}), \quad a(G)(c)(f) = G(c^f),$$

where $a \in |F|$ and $f: T \longrightarrow p(c)$ is a map in \mathcal{S} .

Proposition (2.4). — Let $f: \mathcal{S}' \longrightarrow \mathcal{S}$ be a morphism of \mathfrak{U} -topos and let C be a left exact stack over \mathcal{S} . One has an equivalence of categories

(1) $\operatorname{Top}_{\mathscr{S}}(\mathscr{S}, C - \mathscr{S}) \longrightarrow \operatorname{Stex}_{\mathscr{S}}(C, f_*\operatorname{SH}(\mathscr{S}'))^\circ$, where the domain is the category of morphisms of \mathscr{S} -topos $n: \mathscr{S}' \longrightarrow \mathscr{S}$, where $f_*\operatorname{SH}(\mathscr{S}')$ is the direct image by f of the stack of sheaves over \mathscr{S} (its fiber at $S \in |\mathscr{S}|$ is the category of sheaves over $S'/f^*(S)$) and where the codomain is the opposite of the category of left exact morphisms of stacks $C \longrightarrow f_*\operatorname{SH}(\mathscr{S}')$.

Since C is left exact and $\varepsilon: C \longrightarrow C - \mathscr{S}$ full and faithful, a morphism of topos $n: \mathscr{S}' \longrightarrow C - \mathscr{S}$ is nothing but a left exact functor $n^{-1}: C \longrightarrow \mathscr{S}', n^{-1} = n^* \varepsilon$. Furthermore, since C is left exact there exists a cartesian section p^{-1} of C whose value at $S \in |\mathscr{S}|$ is the terminal object of the fiber C_S and p^{-1} of C is a morphism of sites defining $\pi: C - \mathscr{S} \longrightarrow \mathscr{S}$ since $\pi^*F = Fp$ for any sheaf F on \mathscr{S} . Hence an isomorphism of morphisms of topos $i: \pi \xrightarrow{\sim} f$ is nothing but an isomorphism $i^{-1}: n^{-1}p^{-1} \xrightarrow{\sim} f^*$. In other words the category $\operatorname{Top}_{\mathscr{S}}(\mathscr{S}', C - \mathscr{S})^\circ$ is equivalent to the category M of pairs $(n^{-1}: C \longrightarrow \mathscr{S}', i^{-1}: n^{-1}p^{-1} \xrightarrow{\sim} f)$ where n^{-1} is continuous and left exact. Let $\operatorname{Arr}(\mathscr{S}')$ be the category whose objects are arrows of \mathscr{S}' and let $b: \operatorname{Arr}(\mathscr{S}') \longrightarrow \mathscr{S}', b(X \longrightarrow Y) = Y$. Since every object $c \in |C|$ determines

a terminal map $c \longrightarrow p^{-1}(p(c))$, a pair (n^{-1}, i^{-1}) can be viewed as a functor n': $C \longrightarrow \operatorname{Arr}(\mathcal{S}')$ such that $b \, n' = f * p$ and which is left exact (the continuity condition disappears by $(2.1 \, (1))$). Since b makes a stack over \mathcal{S}' out of the category $\operatorname{Arr}(\mathcal{S}')$, by the very definition of the direct image of a stack, n' is nothing but a functor n'': $C \longrightarrow f_* \operatorname{Arr}(\mathcal{S}')$ and, since n' is left exact, n'' is \mathcal{S} -cartesian and left exact, hence an object of $\operatorname{Stex}_{\mathcal{S}}(C, \operatorname{Arr}(\mathcal{S}'))$. The conclusion follows since $\operatorname{Arr}(\mathcal{S}')$ is equivalent to $\operatorname{SH}(\mathcal{S}')$.

According to the proof, the morphism of topos $n: \mathcal{S}' \longrightarrow C - \mathcal{S}$ which corresponds to a left exact morphism of stacks $n'': C \longrightarrow f_* \operatorname{Arr}(\mathcal{S}')$ is characterized up to unique isomorphism by the equality $n^*\varepsilon = dqn''$

(2)
$$C \xrightarrow{n''} f_* \operatorname{Arr}(\mathcal{S}') \xrightarrow{q} \operatorname{Arr}(\mathcal{S}') \xrightarrow{d} \mathcal{S}'$$

where q is the first projection of $f_* \operatorname{Arr}(\mathcal{S}') = \operatorname{Arr}(\mathcal{S}') \times_{\mathcal{S}'} \mathcal{S}$, d the "domain functor" and ε the Yoneda functor.

Corollary (2.5). — If C is left exact one has an equivalence⁵

(1)
$$\operatorname{Top}_{\mathscr{S}}(\mathscr{S}', C - \mathscr{S}) \longrightarrow \operatorname{Stex}_{\mathscr{S}'}(f^*(C), \operatorname{SH}(S'))^{\circ}.$$

This follows immediately from (2.4), (1.4) and the universal property of the inverse image $f^*(C)$ of C. This gives the *universal property* of $C - \mathcal{S}$ in the bicategory of \mathcal{S} -topos.

Corollary (2.6). $-Let C' = f^*(C)$. One has a commutative square of morphisms of topos

$$C - \mathcal{S} \xleftarrow{C - f} C' - \mathcal{S}'$$

$$\downarrow \qquad \qquad \downarrow$$

$$\mathcal{S} \xleftarrow{f} \mathcal{S}'$$

which is bicartesian.

 $[\]overline{^{5}\text{Stex}_{\mathscr{L}}}(,)$ stands for "category of left exact morphisms of stacks

This means that for any morphism of topos $g: \mathscr{S}'' \longrightarrow \mathscr{S}'$ the functor given by composition with C-f

(2)
$$\operatorname{Top}_{\mathscr{S}'}(\mathscr{S}'', C' - \mathscr{S}') \longrightarrow \operatorname{Top}_{\mathscr{S}}(\mathscr{S}'', C - \mathscr{S})$$

is an equivalence. By the very definition of C' [4] p.87, one has a commutative square

$$\begin{array}{c}
C \xrightarrow{\varphi^{-1}} C' \\
\downarrow p \\
\mathscr{S} \xrightarrow{f^*} \mathscr{S}'
\end{array}$$

where φ^{-1} is cartesian. Furthermore φ^{-1} is left exact by (1.3). By (1.4) and the universal property of $C' = f^*(C)$, for any $g : \mathcal{S}'' \longrightarrow \mathcal{S}'$, the functor

$$\operatorname{Stex}_{S'}(C', g_*\operatorname{SH}(\mathscr{S}'')) \longrightarrow \operatorname{Stex}_S(C, f_*g_*\operatorname{SH}(\mathscr{S}'')), \quad u \longrightarrow u\varphi^{-1},$$

is an equivalence. By (2.4) the proof is now an exercise about universal properties in bicategories.

3. Generating stack of a U-topos

The question of defining a relative notion of generators has been raised by Lawvere and Tierney. We propose here an answer in the language of \mathfrak{U} -topos. It is clear that Prop. (3.3) is still valid when working in their framework and that (3.2) is not.

Definition (3.1). — Let $f: \mathscr{X} \longrightarrow \mathscr{S}$ be a morphism of \mathfrak{U} -topos. A generating stack of f is a full substack C of $F = f_*(\operatorname{Arr}(\mathscr{X}))$ which is small (2.1) and such that, for any $S \in |\mathscr{S}|$ and any $x \in |F_S|$, there exists a covering family $(S_i \longrightarrow S)$, $i \in I$, in \mathscr{S} and for each $i \in I$ a covering family $(c_{i,j} \longrightarrow x_i)$ in the fiber $F_S = \mathscr{X}/f^*(S)$, with $c_{i,j} \in |C|$, where x_i is the inverse image of x by $S_i \longrightarrow S$. A generating stack C is said to be left exact if C and the inclusion functor $i: C \longrightarrow F$ are left exact.

Let us recall that the category of arrows of \mathscr{X} provided with the codomain functor $\operatorname{Arr}(\mathscr{X}) \longrightarrow \mathscr{X}$ is a stack. Hence its direct image F is a stack whose fiber at $S \in |\mathscr{S}|$ is the topos $\mathscr{X}/f^*(S)$ and the inverse image functor $F_u : F_S \longrightarrow F_{S'}$ associated to a map $u : S \hookrightarrow S$ in \mathscr{S} is nothing but pull-back along $f^*(u) : f^*(S') \longrightarrow f^*(S)$.

Hence F is a left exact stack and the condition that a full substack C of F is left exact is that each fiber C_S is stable by finite limits in the fiber F_S .

Proposition (3.2). — Any \mathcal{S} -topos admits a left exact generating stack.

Let us choose a generator S_i , $i \in I \in \mathfrak{U}$, of \mathscr{S} and for each $i \in I$ a full subcategory C_i of F_{S_i} stable by finite limits, generating F_{S_i} and equivalent to a category which belongs to \mathfrak{U} . Let us define C as the full subcategory of F whose objects of projection $S \in |\mathscr{S}|$ are those $x \in |F_S|$ such that there exists a covering family $(c_a : S_a \longrightarrow S)$, such that each S_a is one of the S_i and the inverse image of x by c_a is isomorphic to an object of C_i . This condition being local on \mathscr{S} , it is clear that C is a full substack of F and eve a left exact one since F is left exact. Furthermore C is small since for each $S \in |\mathscr{S}|$ the set of classes of equivalent covering families $(S_a \longrightarrow S)$ as above belongs to \mathfrak{U} . Eventually C is a generating stack since any $S \in |\mathscr{S}|$ can be covered by the S_i .

Proposition (3.3). — Let $\mathscr S$ be a $\mathfrak U$ -topos and C a generating stack of an $\mathscr S$ -topos $f:\mathscr X\longrightarrow\mathscr S$. Then $C-\mathscr S$ is an $\mathscr S$ -topos and there exists an $\mathscr S$ -morphism of topos $n:\mathscr X\longrightarrow C-\mathscr S$ such that $n_*:\mathscr X\longrightarrow C-\mathscr S$ is full and faithful (in other words $\mathscr X$ is a subtopos of $C-\mathscr S$).

3.3.1. We note first that since C is small, $C - \mathcal{S}$ is a \mathfrak{U} -topos. Furthermore there exists a left exact generating stack C' of \mathscr{X} containing C and such that each object of C' is a finite limit of objects of C. Hence the inclusion $C \longrightarrow C'$ induces an equivalence between the \mathscr{S} -topos $\mathbb{C} - \mathscr{S}$ and $C' - \mathscr{S}$ and this fact allows us to assume that C is left exact. Since the inclusion $i:C \longrightarrow F$, $F=f_*\operatorname{Arr}(\mathscr{X})$, is left exact one has an \mathscr{S} -morphism $n:\mathscr{X} \longrightarrow C-\mathscr{S}$, (2.4), whose inverse image functor $n^*:C-\mathscr{S} \longrightarrow \mathscr{X}$ is such that its composition with the Yoneda functor $\varepsilon:C \longrightarrow C-\mathscr{S}$ is equal to the composite of

(1)
$$C \xrightarrow{i} F \xrightarrow{q} Arr(\mathcal{X}) \xrightarrow{d} X, \quad (2.4(2)).$$

For any $c \in |C|$ and any $X \in |\mathscr{X}|$ one has $n_*(X)(c) = \operatorname{Hom}(\varepsilon(c), n_*(X)) = \operatorname{Hom}(n^*\varepsilon(c), X) = \operatorname{Hom}(dqi(c), X) = \operatorname{Hom}_S(i(c), X \times f^*(S))$ where the last set of morphisms is taken in the fiber $\mathscr{X}/f^*(S)$ of F with S = p(c), and the last equal-

ity sign is justified by the definition of F as a fibered product. Hence the formula

(2)
$$n_*: \mathcal{X} \longrightarrow C - \mathcal{S}, \quad n_*(X)(c) = \operatorname{Hom}_{S}(i(c), X \times f^*(S)), \quad S = p(c).$$

3.3.2. To prove that n_* is full and faithful we will first compose it with the inverse $a: C - \mathcal{S} \longrightarrow B_C(\mathcal{S})$ of (2.3 (1))

(3)
$$an_*: \mathscr{X} \longrightarrow B_C(\mathscr{S}), \quad an_*(X)(c) = \mathscr{H}om_S(i(c), X \times f^*(S)),$$

$$S = p(c), c \in |C|,$$

the above formula being justified by (2.3 (2)), where $\mathcal{H}om_S(u,v)$ stands for the sheaf (over S) of S-morphisms between the objects u and v of the fiber at S of the stack F. Let us prove that (3) is the effect on the fibers at the terminal object of \mathcal{S} of a morphism of stacks

(4)
$$m: F \longrightarrow ST(C^V, SH(\mathcal{S})),$$

where ST(A,B) stands for the (split) *stack* or morphisms of stacks between A and B (internal Hom in the bicategory of stacks [4] p.57, 77), whose fiber at $S \in |\mathcal{S}|$ is the category of morphisms $A/S \longrightarrow B$ of stacks over \mathcal{S}/S . We obtain (4) by composition of

(5)
$$F \xrightarrow{y} ST(F^{V}, SH(\mathcal{S})) \xrightarrow{j} ST(C^{V}, SH(\mathcal{S}))$$

where j is induced by composition with $i: C \longrightarrow F$ and where y is a "relative Yoneda functor" defined by

(6)
$$y(a)(b) = \mathcal{H}om_{S}(b, a^{f})$$

where $f: T \longrightarrow S$ is a map in \mathscr{S} and $a \in |F_S|$, $b \in |F_T|$. One should note that the restriction of y to the terminal fiber of F is also the restriction of the composite $F \stackrel{\varepsilon}{\longrightarrow} F - \mathscr{S} \stackrel{a}{\longrightarrow} B_F(\mathscr{S})$, (2.1(3)), (2.3(2)). By localisation it follows that the restriction of y to each fiber is full and faithful hence y is such. On the other hand, since any object of F can be covered for the canonical topology of F by objects of i(C) and since i is full and faithful it is easy to show that j is also full and faithful and the conclusion follows.

Proposition (3.4). — Fibered products exist in the bicategory of \mathfrak{U} -topos.

according to (3.2) and (3.3) any morphism of \mathfrak{U} -topos $\mathscr{X} \longrightarrow \mathscr{S}$ can be factored in $\mathscr{X} \stackrel{n}{\longrightarrow} C - \mathscr{S} \stackrel{\pi}{\longrightarrow} \mathscr{S}$ where n_* is full and faithful and where C is a left exact small stack over \mathscr{S} . By (2.6) the pullback of π along any morphism of \mathfrak{U} -topos $f: \mathscr{S}' \longrightarrow \mathscr{S}$ exists. On the other hand the pull-back of n along any morphism of \mathfrak{U} -topos $y: \mathscr{Y} \longrightarrow C - \mathscr{S}$ exists because \mathscr{X} is a subtopos of $C - \mathscr{S}$ hence is defined by some topology J on $C - \mathscr{S}$ and it suffices to take as a pullback the subtopos of \mathscr{Y} defined by the finest topology J' on \mathscr{Y} such that the inverse image functor $y^*: C - \mathscr{S} \longrightarrow \mathscr{Y}$ is continuous. The conclusion follows by transitivity of pullback in a bicategory.
